RI/MOM Schemes (RI = Regularisation Independent; MOM = Momentum Subtraction)

[Martinelli et al '95]: mimick the procedure in perturbation theory:

- choose Landau gauge

\[ \partial_\mu A_\mu = 0 \]

- can be implemented on the lattice by a minimisation procedure

- RI/MOM schemes are very popular: many major collaborations use it because
  - it is straightforward to implement on the lattice; many improvements over the years regarding algorithmic questions
  - it can be used on the very same gauge configurations which are produced for hadronic physics

- Regularisation Independence (RI) means: correlation functions of a renormalised operator do not depend on the regularisation used (up to cutoff effects).
Suppose we have calculated a renormalised hadronic matrix element of the multiplicatively renormalisable operator $O$

$$\mathcal{M}_O(\mu) = \lim_{a \to 0} \langle h | O_{R}(\mu) | h' \rangle$$

Provided $\mu$ is in the perturbative regime, one may evaluate the MOM scheme in continuum perturbation theory and evolve to a different scale:

$$\mathcal{M}_O(\mu') = U(\mu', \mu) \mathcal{M}_O(\mu),$$

$$U(\mu', \mu) = \exp \left\{ \int \frac{\gamma_O(g)}{\beta(g)} d g \right\}$$

N.B. Continuum perturbation theory is available to 3-loops in some cases!
The scale $\mu$ could be too low; need to hope for a “window”

$$\Lambda_{\text{QCD}} \ll \mu \ll a^{-1}$$

In practice scales are often too low: non-perturbative effects (e.g. pion poles, condensates) are then eliminated by fitting to expected functional form (from OPE in fixed gauge);

$\Rightarrow$ errors are difficult to quantify!

- Gribov copies: the (Landau) gauge condition does not have a unique solution on the full gauge orbit
- Perturbative calculations are made using
  - infinite volume
  - vanishing quark masses

$\Rightarrow$ difficult for numerical simulations especially in full QCD.
A prominent non-perturbative effect: the pion pole

[Martinelli et al. '95 ]

- Consider the 3-point correlation function for $P^a$:

$$\int d^4x \int d^4y \, e^{-ipx} \langle \bar{\psi}(0)\gamma_5 \frac{1}{2}\tau^b \psi(x) P^a(y) \rangle$$

- For large $p^2$ it is dominated by short distance contributions either at $x \approx 0$ or $x \approx y$. The contribution for $x \approx 0$ is proportional to the pion propagator

$$\int d^4y \langle P^b(0)P^a(y) \rangle \propto \frac{1}{m^2_\pi}$$

- Dimensional counting: suppression by $1/p^2$ relative to the perturbative term at $x \approx y$:

$$Z_P^{\text{MOM, non-pert}} \sim \frac{A}{\mu^2 m_q} + \ldots$$

$\Rightarrow$ the chiral limit is ill-defined!
$Z^{-1}_P$ for the RGI operator after subtraction of the pion pole through a fit. While there is no plateau at fixed $\beta$, the situation seems to improve towards higher $\beta$, as $\mu$ gets larger in physical units.
RI/MOM scheme, example 2

[ETMC collaboration, talk by P. Dimopoulos at Lattice ’07 ]

twisted mass QCD with \( N_f = 2 \), subtraction of pion pole à la

[Giusti, Vladikas ’00 ]

While \( Z_S \) shows the expected plateau, \( Z_P \) shows some slope even after subtraction of the pion pole (cutoff effects?)
RI/MOM scheme, example 2

[R. Babich et al. 06] four-quark operator for $B_K$ with overlap quarks (quenched QCD at $\beta = 6.0$):

- non-perturbative effects are eliminated through fit function from OPE including logarithmic terms
Comparison of the quark vertex function in Landau gauge, fixed in two different ways on the same ensemble of gauge configurations

Influence of Gribov copies can be sizable!
There are examples where the method seems to work fine.

Non-perturbative effects like the pion pole are either subtracted or taken into account by fits to the expected $p^2$-behaviour; but error estimates seem difficult!

A warning from the quark-gluon vertex: the effect of Gribov copies should be monitored!

Finite volume and quark mass effects often small.

Since the method can be applied at relatively little cost on the existing configurations (unless charm quark is dynamical!) it can always be tried!

However, it seems difficult to get reliable errors down to the desired level (say below 1 percent for $Z$-factors)
Many improvements have been introduced over the last 10–15 years (cf. lattice 2009 review by Y. Aoki): A selection:

- use of non-exceptional momentum configurations (P. Boyle, Lattice 2007):
  reduces the problem with Goldstone poles;
  Continuum perturbation theory needs to be re-done!

- reach higher scales? Small steps may be possible [Arthur & Boyle '10 ]; in principle need to promote to finite volume scheme: fix $\mu L$:
  - need gauge fixing on the torus (complicated)
  - twisted gauge field boundary conditions? link $N_c$ with $N_f$
  - in any case perturbation theory needs to be re-done from scratch and may be complicated

- use gauge invariant correlation functions $\Rightarrow$ no trouble with Gribov copies; but more demanding in perturbation theory;
  expect larger cutoff effects on dimensional grounds.

- Perturbative subtraction of cutoff effects

...
The problem of large scale differences

Λ and $M_i$ refer to the high energy limit of QCD

- The scale $\mu$ must reach the perturbative regime: $\mu \gg \Lambda_{\text{QCD}}$
- The lattice cutoff must still be larger: $\mu \ll a^{-1}$
- The volume must be large enough to contain pions: $L \gg 1/m_\pi$
- Taken together a naive estimate gives

$$\frac{L}{a} \gg \mu L \gg m_\pi L \gg 1 \quad \Rightarrow \quad \frac{L}{a} \simeq O(10^3)$$

⇒ widely different scales cannot be resolved simultaneously on a finite lattice!
...and its solution

- widely different scales cannot be resolved simultaneously on a single finite lattice
  ⇒ break-up in smaller steps [Lüscher, Weisz, Wolff '91; Jansen et al. '95]:
  1. define renormalized parameters that run with the space-time volume, i.e. $\mu = 1/L$
  2. match to the chosen hadronic input at a hadronic scale $m_\rho L_{\text{max}} = O(1)$
  3. Non-perturbative renormalization group: recursively connect scales $L = 1/\mu$ and $2L = 1/(\mu/2)$,
     \[ L \rightarrow 2L \rightarrow 4L \rightarrow 8L \ldots \]
  4. once arrived in the perturbative regime (to be checked)
     convert perturbatively e.g. to the \( \overline{\text{MS}} \) scheme
Requirements

Wanted: renormalization scheme which
- is defined in a finite space-time volume
- is non-perturbatively defined;
- can be expanded in perturbation theory (up to 2-loop) with reasonable effort;
- is gauge invariant;
- is quark mass-independent.
- can be evaluated by numerical simulation!

⇒ use the Schrödinger functional!
The Schrödinger functional (formal continuum)

The Schrödinger functional appears naturally in the Schrödinger representation of QFT (Symanzik ’81), as the time evolution kernel when integrating the functional Schrödinger equation:

Wave functional in Dirac’s notation ($A, A'$: field configurations at (Euclidean) times 0, $T$):

$$\psi[A] \equiv \langle A|\psi \rangle$$

$$\psi'[A'] = \int D[A] \langle A'|e^{-T\mathcal{H}}|A\rangle \langle A|\psi \rangle$$

The Schrödinger functional is a functional of the initial and final field configuration:

$$\mathcal{Z}[A, A'] = \langle A'|e^{-T\mathcal{H}}|A\rangle = \int D[\phi]e^{-S}.$$  

The Euclidean field $\phi$ satisfies Dirichlet boundary conditions

$$\phi(x)|_{x_0=0} = A(x) \quad \phi(x)|_{x_0=T} = A'(x)$$
The Schrödinger functional is an example of a field theory defined on a manifold with boundary ⇒ problems/questions:

- Translation invariance is broken ⇒ momentum is not conserved.
- Conventional proofs of perturbative renormalisability rely on power counting theorems in momentum space: not applicable here!
- Heuristic arguments by Symanzik:

A renormalisable QFT remains renormalisable when considered on a manifold with boundary. Besides the usual parameter and field renormalisations one just needs to add a complete set of **local boundary counterterms** to the action, i.e. polynomials in the fields and its derivatives of dimension 3 or less, integrated over the boundary.

In the case of scalar $\phi^4$-theory and boundary at $x_0 = 0$ one finds:

$$\int_{x_0=0} d^3x \, \phi^2, \quad \int_{x_0=0} d^3x \, \phi \partial_0 \phi$$
The definition for gauge theories and QCD is analogous: The Schrödinger functional is the functional integral on a hyper cylinder,

$$Z = \int \text{fields} e^{-S}$$

with periodic boundary conditions in spatial directions and Dirichlet conditions in time.

**Boundary conditions for gluon and quark fields:**

$$P_{\pm} = \frac{1}{2} (1 \pm \gamma_0),$$

$$P_+ \psi(x)|_{x_0=0} = \rho \quad P_- \psi(x)|_{x_0=T} = \rho'$$

$$\bar{\psi}(x) P_-|_{x_0=0} = \bar{\rho} \quad \bar{\psi}(x) P_+|_{x_0=T} = \bar{\rho}'$$

$$A_k(x)|_{x_0=0} = C_k \quad A_k(x)|_{x_0=T} = C'_k$$
Correlation functions are then defined as usual

\[ \langle O \rangle = \left\{ Z^{-1} \int_{\text{fields}} O \, e^{-S} \right\}_{\rho = \rho' = 0; \bar{\rho} = \bar{\rho}' = 0} \]

\[ O \] may contain quark boundary fields

\[ \zeta(x) \equiv P_- \zeta(x) = \frac{\delta}{\delta \bar{\rho}(x)} \]

\[ \overline{\zeta}(x) \equiv \overline{\zeta}(x) P_+ = - \frac{\delta}{\delta \rho(x)} \]

\[ \zeta'(x) \equiv P_+ \zeta'(x) = \frac{\delta}{\delta \bar{\rho}'(x)} \]

\[ \overline{\zeta}'(x) \equiv \overline{\zeta}'(x) P_+ = - \frac{\delta}{\delta \rho'(x)} \]

⇒ the boundary values of the quark fields are used as external sources
Properties of the QCD Schrödinger functional

- The SF is renormalisable: besides the renormalisation of the coupling and quark masses, the boundary quark fields require a multiplicative renormalisation.
- Absence of fermionic zero modes: numerical simulations at zero quark masses are possible!
- For some choices of $C_k$ and $C'_k$ it can be shown that the induced background gauge field is an absolute minimum of the action $\Rightarrow$ perturbation theory is straightforward and seems practical at least to 2-loop order.
- As $C_k$ and $C'_k$ are held fixed only spatially constant gauge transformations are possible at the boundaries:

$$C_k(x) \rightarrow \Lambda(x) C_k(x) \Lambda^{-1}(x) + \Lambda(x) \partial_k \Lambda^{-1}(x)$$

i.e. the allowed $\Lambda(x) \in SU(N)$ must be $x$-independent and commute with $C_k$. 
Therefore, bilinear boundary quark sources such as

\[ \mathcal{O}^a = \int d^3y d^3z \, \overline{\zeta}(y) \gamma_5 \frac{\tau^a}{2} \zeta(z), \quad \mathcal{O}'^a = \int d^3y d^3z \, \overline{\zeta}'(y) \gamma_5 \frac{\tau^a}{2} \zeta'(z) \]

are gauge invariant!

Typical **gauge invariant** correlation functions are then

\[ f_P(x_0) = -\frac{1}{3} \sum_{a=1}^{3} \langle P^a(x) \mathcal{O}^a \rangle, \quad f_A(x_0) = -\frac{1}{3} \sum_{a=1}^{3} \langle A^a_0(x) \mathcal{O}^a \rangle, \]
⇒ convenient in perturbation theory: in contrast to a periodic or infinite volume where gauge invariant fermionic correlation functions lead to one-loop diagrams at lowest order, e.g.

\[ g_{PP}(x_0) = -a^3 \sum_x \sum_{a=1}^{3} \langle P^a(x)P^a(0) \rangle \]

- dimensional analysis ⇒ at short distances one finds the asymptotic behaviour (up to logarithms):

\[ g_{PP}(x_0) \sim \frac{\text{const}}{(x_0)^3}, \quad f_P(x_0) \sim \text{const} \]

- expect
  - small cutoff effects for \( f_P(x_0) \) due to mild \( x_0 \)-dependence
  - good signal in numerical simulations.
More on the renormalisability of the SF

- no gauge invariant dimension $\leq 3$ counterterm exists, the pure gauge SF is finite after renormalisation of the coupling constant
- continuum quark action with SF boundary conditions at tree-level:

$$S_f = \int d^4x \, \overline{\psi} \left( \frac{1}{2} \not \! D + m \right) \psi - \frac{1}{2} \int_{x_0=0} d^3x \, \overline{\psi} \psi - \frac{1}{2} \int_{x_0=T} d^3x \, \overline{\psi} \psi$$

Exercise:
Show that the boundary terms are necessary if one requires the existence of smooth solutions to the equations of motion with SF boundary conditions

- The counterterms are linear in the boundary fields

$$\overline{\psi}(x)\psi(x)|_{x_0=0} = \bar{\rho}(x) P_- \psi(0, x) + \overline{\psi}(0, x) P_+ \rho(x),$$

$$\overline{\psi}(x)\psi(x)|_{x_0=T} = \bar{\rho}'(x) P_+ \psi(T, x) + \overline{\psi}(T, x) P_- \rho'(x),$$
The only dimension 3 counterterm with correct symmetries is $\bar{\psi}\psi$.

Time reversal symmetry requires the same coefficient at $x_0 = 0, T$.

This counterterm can thus be absorbed in a multiplicative rescaling of $\rho, \rho', \bar{\rho}, \bar{\rho}'$ by the same renormalization constant:

$$\rho_R = Z_\rho \rho, \quad \bar{\rho}_R = Z_\rho \bar{\rho}, \quad \rho'_R = Z_\rho \rho', \quad \bar{\rho}'_R = Z_\rho \bar{\rho}'$$

Consequently, setting $Z_\zeta = Z_\rho^{-1}$:

$$\zeta_R = Z_\zeta \zeta, \quad \zeta'_R = Z_\zeta \zeta', \quad \bar{\zeta}_R = Z_\zeta \bar{\zeta}, \quad \bar{\zeta}'_R = Z_\zeta \bar{\zeta}'$$

Hence sources like $O^a$ are multiplicatively renormalised by $Z_\zeta^2$.
Definition of the SF coupling [Lüscher et al. '92]

- Choose abelian and spatially constant boundary gauge fields:

  \[ C_k = \frac{i}{L} \left( \begin{array}{ccc} \phi_1 & 0 & 0 \\ 0 & \phi_2 & 0 \\ 0 & 0 & \phi_3 \end{array} \right), \quad C'_k = \frac{i}{L} \left( \begin{array}{ccc} \phi'_1 & 0 & 0 \\ 0 & \phi'_2 & 0 \\ 0 & 0 & \phi'_3 \end{array} \right), \quad k = 1, 2, 3 \]

- with angles taken to be linear functions of a parameter \( \eta \):

  \[ \phi_1 = \eta - \frac{\pi}{3}, \quad \phi'_1 = -\phi_1 - \frac{4\pi}{3}, \]
  \[ \phi_2 = -\frac{1}{2} \eta, \quad \phi'_2 = -\phi_3 + \frac{2\pi}{3}, \]
  \[ \phi_3 = -\frac{1}{2} \eta + \frac{\pi}{3}, \quad \phi'_3 = -\phi_2 + \frac{2\pi}{3}. \]

- The gauge action has an absolute minimum for:

  \[ B_0 = 0, \quad B_k = \left[ x_0 C'_k + (L - x_0) C_k \right] / L, \quad k = 1, 2, 3. \]

  i.e. other gauge fields with the same action must be gauge equivalent to \( B_\mu \)
Definition of the SF coupling

- Define the effective action of the induced background field

\[ \Gamma[B] = - \ln \mathcal{Z}[C, C'] \]

- In perturbation theory the effective action has the expansion

\[ \Gamma[B] \sim g_0^{-2} \Gamma_0[B] + \Gamma_1[B] + O(g_0^2) \]

- Definition of the SF coupling:

\[ \bar{g}^2(L) = \left. \frac{\partial \eta \Gamma_0[B]}{\partial \eta \Gamma[B]} \right|_{\eta=0} \bigg|_{m_{q,i}=0} \Rightarrow \bar{g}^2(L) = g_0^2 + O(g_0^4) \]

- b.c.’s induce a constant colour electric field:

\[ G_{0k} = \partial_0 B_k = \frac{C_k - C'_k}{L} \]

\[ \Rightarrow \] The coupling is defined as “response coefficient” to a variation of a constant colour electric field.
